# Geoid Heights Computation from GPS Data and Classical Terrestrial Zenith Angle Observations 

Metin SOYCAN and Arzu SOYCAN, Turkey

Key words: GPS, geoid, zenith angle, height

#### Abstract

SUMMARY In many surveying and engineering applications, orthometric heights are required. GPS derived heights refer to an ellipsoid and not to the geoid as orthometric heights. Ellipsoidal heights have geometric meanings in practical surveying, engineering, geophysics and in other applications, and they bear no physical meanings. To have ellipsoidal heights converted into orthometric heights, precise geoid heights are required. Several techniques can be used for determination of geoid heights. Most commonly used method for the determination of geoid is the combination of GPS data and leveling measurements. Despite the fact that geometric leveling is in general easy and practicable, it is a measurement method that is hard and uneconomic to apply particularly in mountainous, hilly and rugged areas. This study aims the use of conventional terrestrial zenith angle and GPS data instead of GPS-geometric leveling for the determination of precise geoid heights. The method has been probed into in consideration of the accuracy, practicability, measurement and evaluation criteria, and has been examined. In addition, geoid profiles that have been determined with the GPSZenith(GPS_ZEN.) angles measurement have been compared with TG-99A and IGNA geoid models to explore its consistency.

## SUMMARY IN TURKISH

Bir çok ölçme ve mühendislik uygulaması ortometrik yükseklik bilgisini gerektirir. GPS ile elde edilen yükseklikler elipsoidal yüksekliklerdir. Elipsoidal yükseklikler, geometrik anlamlı büyüklükler olup fiziksel anlam içermezler. Elipsoidal yüksekliklerin ortometrik yüksekliklere çevrilmesi jeoit yüksekliği bilgisi gerektirmektedir. Jeoit yükseklikleri çeşitli tekniklerle belirlenebilir. En yaygın kullanılan jeoit yüksekliği belirleme tekniği GPS ve Geometrik Nivelman ölçülerinin kombinasyonudur. Geometrik nivelman oldukça basit ve kolay olmasına karşın, özellikle dağlık ve engebeli arazilerde, uygulaması zor ve ekonomik olmayan bir seçenektir. Bu çalışmada, hassas jeoit yüksekliklerinin GPS-Geometrik nivelman yerine GPS ve klasik yersel zenit açıları ölçmelerinin kullanılması ile belirlenmesi amaçlanmıştır. Yöntem uygulanabilirlik, doğruluk, ölçme ve değerlendirme kriterleri bakımından ele alınmış ve irdelenmiştir. Ayrıca, GPS-Zenit açı ölçmeleri ile bir geoid profili belirlenmiş ve mevcut TG99A ve IGNA jeoit modelleri ile uyuşumu incelenmiştir.

# Geoid Heights Computation from GPS Data and Classical Terrestrial Zenith Angle Observations 

Metin SOYCAN and Arzu SOYCAN, Turkey

## 1. INTRODUCTION

Parallel to the development of satellite techniques and computation methods, GPS-Levelling method has become effectively usable for geodetic studies as well as for many specific areas. Particularly after the 1990s, there is increase in initiatives and studies aimed at obtaining geoid with "cm" accuracy. They differ in the determination of geoid heights, method, data used, practicability and accuracy. Frequently using methods in practice can be ordered as below;

- Global models, constituted from potential coefficients
- Use of vertical deflection, obtained from astro-geodetic measurement
- Gravimetric measurement,
- GPS-Geometric levelling,
- GPS-Precise trigonometric levelling,
- GPS-Astronomic observation,
- GPS- Gravimetric measurement,

Geoid surface is formed of components with various wave lengths depending on handling size. An area larger than 1000 km is expressed as long wave length geoid components, areas between $200-1000 \mathrm{~km}$ as medium wave length, areas between $100-20 \mathrm{~km}$ as short wave length and areas under 20 km as ultra-short wave length geoid components. In recent applications, approaches were adopted to determine long wave length effects utilizing the earth's potential coefficients, medium wave length effects utilizing gravity, and short and ultra-short wave length effects utilizing combined methods (Aksoy et all 1999, Deniz et all 2001, Ollikainen 1997, Schödlbauer et all 1992).

The most effective technique used in practice particularly for the determination of short and ultra-short wave length components is the GPS-leveling technique. With the GPS-leveling method, it is possible to determine geoid heights with $3-5 \mathrm{~cm}$ absolute accuracy. This accuracy is relatively much higher. Besides, this method is one that is accepted and applied by the whole world due to its measurement, ease of computation and its economic application (Ayan et all 2001, Featherstone et all 1998, IGNA 1999, IAG 1995, Zhan and Yong 1999, Park 1998, Rapp 1992, Forsberg 1990).

In GPS-leveling method, it is possible to determine ellipsoidal heights with sufficient accuracy using relative GPS measurements. As for the orthometric heights, they are widely determined by geometric leveling. Despite the fact that GPS-geometric leveling has high precision, it might not be practical and economical in mountainous, hilly and rugged areas. The simple and economic alternative method that might be used in such regions is the combination of GPS measurement with precise zenith angle measurements. This method is more flexible than GPS-geometric levelling and reaches the GPS-geometric leveling accuracy
by observing the zenith angle measurements carefully, precisely, simultaneously and reciprocally using a special surveying equipments by selecting the length of sight shorter than 500 m and precise relative static GPS observation (Aksoy et all, 1993, Kuntz and Schmitt 1986, Rüeger and Brunner 1981, Rüeger and Brunner 1982, Schödlbauer et all 1992, Tilk,Thies 1986, Soycan 2002, Soycan 2004).

## 2. MATHEMATICAL MODEL OF THE PROPOSED METHOD

In this method, it is necessary that observing the zenith angles by simultaneously and reciprocally, for elimination of some systematic errors like refraction and curvature of the earth, between two neighboring points. GPS-derived baseline vector components, between two neighboring points can be available by direct observation and processing of relevant baseline or computation of the baseline components from differences of cartesian coordinates of points. As depend on GPS-derived baseline components $\Delta \mathrm{X}_{\mathrm{ik}}, \Delta \mathrm{Y}_{\mathrm{ik}}, \Delta \mathrm{Z}_{\mathrm{ik}}$, ellipsoidal longitude and latitude $\varphi_{\mathrm{i}}, \lambda_{\mathrm{i}}$ ve $\varphi_{\mathrm{k}}, \lambda_{\mathrm{k}}$. Equation (1) can be written for the $\zeta_{\mathrm{ik}}, \zeta_{\mathrm{ki}}$ ellipsoidal zenith angles, and the slope distance between the points $P_{i}$ and $P_{k}$ (Schödlbauer et all 1992).

$$
\begin{gather*}
\zeta_{\mathrm{ik}}=\arccos \left(\left(\cos \varphi_{\mathrm{i}}\left(\cos \lambda_{\mathrm{i}} \Delta \mathrm{X}_{\mathrm{ik}}+\sin \lambda_{\mathrm{ik}} \Delta \mathrm{Y}_{\mathrm{ik}}\right)+\sin \varphi_{\mathrm{i}} \Delta \mathrm{Z}_{\mathrm{ik}}\right) / \mathrm{D}_{\mathrm{ik}}\right) \\
\zeta_{\mathrm{ki}}=\arccos \left(\left(\cos \varphi_{\mathrm{k}}\left(\cos \lambda_{\mathrm{k}} \Delta \mathrm{X}_{\mathrm{ki}}+\sin \lambda_{\mathrm{ki}} \Delta \mathrm{Y}_{\mathrm{ki}}\right)+\sin \varphi_{\mathrm{k}} \Delta \mathrm{Z}_{\mathrm{ki}}\right) / \mathrm{D}_{\mathrm{ik}}\right)  \tag{1}\\
\mathrm{D}_{\mathrm{ik}}=\sqrt{\left(\Delta \mathrm{X}_{\mathrm{ik}}^{2}+\Delta \mathrm{Y}_{\mathrm{ik}}^{2}+\Delta \mathrm{Z}_{\mathrm{ik}}^{2}\right)}
\end{gather*}
$$

Figure.1. Ellipsoidal zenith angle and vertical deflections(Schödlbauer et all 1992)
Averaging the reciprocal ellipsoidal zenith angles $\zeta_{\mathrm{ik}}, \zeta_{\mathrm{ki}}$ as well as $\varphi_{\mathrm{i}}, \lambda_{\mathrm{i}}$ ve $\varphi_{\mathrm{k}}, \lambda_{\mathrm{k}}$, yields the ellipsoidal zenith angle $\zeta_{0}$ in the middle of the line $\mathrm{P}_{\mathrm{i}}-\mathrm{P}_{\mathrm{k}}$;

$$
\begin{gather*}
\zeta_{0}=\arccos \left(\left(\cos \varphi_{0}\left(\cos \lambda_{0} \Delta \mathrm{X}_{\mathrm{ik}}+\sin \lambda_{0} \Delta \mathrm{Y}_{\mathrm{ik}}\right)+\sin \varphi_{0} \Delta \mathrm{Z}_{\mathrm{ik}}\right) / \mathrm{D}_{\mathrm{ik}}\right) \\
\varphi_{0}=\frac{\varphi_{\mathrm{i}}+\varphi_{\mathrm{k}}}{2}, \lambda_{0}=\frac{\lambda_{\mathrm{i}}+\lambda_{\mathrm{k}}}{2} \tag{3}
\end{gather*}
$$

$\mathrm{Z}_{\mathrm{ik}}$ and $\mathrm{Z}_{\mathrm{ki}}$ are simultaneously and reciprocally observed zenith angles by conventional terrestrial techniques. Similarly averaging the $\mathrm{Z}_{\mathrm{ik}}$ and $\mathrm{Z}_{\mathrm{k}}$, the refraction free zenith angle $\mathrm{Z}_{0}$ can be obtained in the middle of the line $P_{i}-P_{k}($ Schödlbauer et all 1992).

$$
\begin{equation*}
\mathrm{Z}_{0}=\frac{\left(\mathrm{Z}_{\mathrm{ik}}+200^{\mathrm{g}}-\mathrm{Z}_{\mathrm{ki}}\right)}{2} \tag{4}
\end{equation*}
$$

Thus, is the deflection of the vertical $\varepsilon_{0}$ in the azimuth $\alpha_{i k}$ of the profile $\mathrm{P}_{\mathrm{i}}-\mathrm{P}_{\mathrm{k}}$ can be available.

$$
\begin{equation*}
\varepsilon_{0}=Z_{0}-\zeta_{0} \tag{5}
\end{equation*}
$$

Geoid height difference $\Delta \mathrm{N}_{\mathrm{ik}}$ between $\mathrm{P}_{\mathrm{i}}$ and $\mathrm{P}_{\mathrm{k}}$ can be written as below;

$$
\begin{equation*}
\Delta \mathrm{N}_{\mathrm{ik}}=\mathrm{D}_{\mathrm{ik}} \sin \mathrm{Z}_{0} \sin \varepsilon_{\mathrm{ik}} \tag{6}
\end{equation*}
$$

## 3. APPLICATION AND EVALUATION OF THE MODEL IN A TEST AREA

As for the test area, it has been chosen a profile between Beykoz and Riva, which is more rugged and hilly area. The length of this profile is about 16 km , and its geoid height difference has been calculated as 55 cm from our initial study. Geoid height change in 1 km is about 3.5 cm . Profile points have been chosen in places where it is possible to determine land topography in detail, and where GPS, zenith angles and levelling measurements may be made easily. The profile has been planned as 87 points on a route of about consecutive 16 kilometers seeing each other extending along the Beykoz-Riva link highway. There are 6 IGNA reference points along the profile with known coordinates in the ITRF-94 (International Referance Frame-1994) and ED-50 (Europan Datum 1950) system.

Figure.2. View of the profiles in horizontal plane

[^0]IGNA has been formed with 34 primary points that have been chosen in addition to 5 TUTGA (Turkish National Fundamental GPS Network), 8 TUTNA (Turkish National Control Network) point, 7 Istanbul Metropolitan Geodetic Network points in connection with the TUTGA and the TUTNA, with side lengths of $15-20 \mathrm{~km}$, covering the municipal borders of city of Istanbul. Total number of points is formed of 650 benchmark measured in connection with the primary network. IGNA network has been designed, measured and evaluated in two parts, being primary network points and densification network (Ayan et all 2001, IGNA 1999).

In test area, for equipment with sufficient precision to allow the measurement of zenith angle measurements simultaneously and reciprocally, special target signs mounted on Wild-T2 theodolites' objective lens. In both theodolites, a red tape pasted on the objective lens in ' + ' form has been used as target sign. The part at the center of the sign is cut to allow the theodolites to see each other and the center of target will be made clear. Therefore, a target mark has been formed that is able to achieve the condition of simultaneously and reciprocally measurement of zenith angles, that is formed easily and economically, that is ideal for observation, and that will minimize targeting error. By using this equipment two full series zenith angles are observed between adjacents points on the geoid profile.

Figure.3. Observation of reciprocally and simultaneously zenith angles by Wild-T2 theodolite with special target

The study also made use of three Z-Surveyor GPS receivers made by Ashtech firm with geodetic antennas, Wild-NAK2 levelling instrument, a special mira partitioned in mm , Golden software Surfer, Excel and Matlab computation software, Winprism and Bernese GPS processing software.

Each of the 87 points chosen along the profile has been measured from at least two IGNA points with 30 -minute sessions using the static method. From 6 IGNA points, a total of 174 baseline vectors have been measured and processed.

Table.1. Surveying configuration of GPS network

| Survey mode: Static observation with 2 referance on IGNA points, third receiver rover on the points |  |  |
| :---: | :---: | :---: | :---: |

for each campaign\end{array}\right]\)

To determine the base vector measurement accuracy and to subject the processed baseline vectors to quality control, 174 baseline vector lengths measured between the points on IGNA Points and the profile and standard deviations have been examined. As a result of evaluations, $5.8 \mathrm{~mm}+2 \mathrm{ppm}$ equation has been obtained as baseline vector measurement accuracy.After making an outlier search in the GPS network, baseline vectors have been adjusted taking the coordinates of the 6 IGNA point as fixed. Summary information is given about adjustment results in Table 2. One can say that the accuracies of ellipsoidal heights obtained accordingly are about 9 mm .

Table.2. Processing and adjustment informations of GPS network

| GPS Network informations |  |
| :---: | :---: |
| Number of fixed points (XYZ fixed) | 6 |
| Number of total points (k) | 93 |

From Table 3 to Table 7 show geoid heights computation of profile points. Bold numeral type is geoid height clousere for each profile line and italic numeral type is known geoid height of IGNA reference points.

## 4. COMPARATION OF PROFILE WITH IGNA AND TG-99A MODELS

The 87-point 16 km GPS_GL and GPS_PTL geoid profile have been compared with the IGNA and TG-99A geoid models summarized below.

IGNA geoid model were utilized to determine "cm" accuracy geoid by GPS and GL data, within the borders of Istanbul municipality, 458 geoid base points covering the said region has been taken in an area of $65 \times 160 \mathrm{~km}$. IGNA geoid model has been determined using the multi parameter regression method for practical use. Geoid heights, calculated from GPS and GL measurements, are modeled as two-parameter surface polynomial, which is in fifth order. The accuracy of the model is tested via independent levelling and GPS measurements different parts of Istanbul. As a result of studies made for the accuracy of the model, model consistency has been found to be about $\pm 4 \mathrm{~cm}$. As for relative accuracy, it may be obtained higher than this value (Ayan et all 2001, Deniz et all 2001, IGNA 1999).

As for the TG-99A geoid model, it has been computed at the $3^{\prime} \times 3^{\prime}$ grid frequency through modeling of differences on GPS-Levelling points of long wavelength effects in the Turkish Gravimetric Geoid (TG-91) computed in 1991. GPS coordinates ( $\varphi, \lambda, h$ ) and orthometric heights $(\mathrm{H})$ of 197 points and the $3^{\prime} \times 3^{\prime}$ grid value used in TG-91 has been used. GPS-Levelling geoid heights were obtained from the difference between the GPS ellipsoidal heights and the orthometric height values. As for the gravimetric geoid heights belonging to the same points, they have been determined using the minimum curvature interpolation method with 6 parameters trend surface. As a basic data, the study used the difference between gravimetric geoid height and GPS-Levelling geoid height. During the evaluation stage, 1 point was removed due to inconsistency, and 196 points were used. The inner accuracy of model is achieved in $\pm 5 \mathrm{~cm}$ from the difference between interpolated and measured geoid heights for 196 points. Furthermore, the accuracy of the model is tested in 122 independent points throughout Turkey, and the outer geoid height accuracy has been found to be $\pm 10 \mathrm{~cm}$. It is possible to obtain values with relatively higher accuracy values (TUTGA-99A, 1999).

[^1]

|  | (GPS_ZEN)-(TG-99A) | (GPS_ZEN.)-(IGNA) |
| :---: | :---: | :---: |
| Absolute value of the Minimum difference $(\mathrm{m})$ | 0.001 | 0.001 |
| Absolute value of the Maximum difference $(\mathrm{m})$ | 0.093 | 0.085 |
| Avarege of absolute difference $(\mathrm{m})$ | 0.028 | 0.036 |
| Standart deviataion of average of difference $(\mathrm{m})$ | 0.020 | 0.023 |
| RMS value of the difference $(\mathrm{m})$ | 0.034 | 0.043 |

Figure.7. Comparation of the (GPS_ZEN) with IGNA and TG-99A model

Differences obtained as a result of comparison of the geoid heights obtained using the GPS_GL and GPS_PTL methods with the geoid heights interpolated from TG-99A and IGNA geoid model are given in Figure 7.

## 5. CONCLUSION

In length of sight shorter than 500 meters, one may accept that the effect of deviation of verticle on height is negligibly small. In this regard, to determine geoid heights by using proposed models zenith angle measurements are made with short lengths of sight.
The most important remaining effect is the refraction effect, by choosing the length of sights between points short, and by making simultaneous and reciprocal zenith angle observations by using special equipment in favorable meteorological conditions, this effect may be reduced to a great extent.
When appropriate measurement and processing strategies are applied with the GPS, it is possible to determine ellipsoidal heights with an accuracy of about 9 mm (Max. 13mm).
Consistency of geoid profile determined with the GPS_ZEN. with the IGNA geoid is 43 mm (Max. 85 mm , Min. 1mm), while its consistency with the TG-99A geoid is 34 mm (Max. 93 mm , Min. 1 mm ).
In GPS-levelling method; it is possible to determine ellipsoidal heights with sufficient accuracy using relative GPS measurements. As for the orthometric heights, they are widely determined by GL. Despite the fact that GL has high precision, it might not be practical and economical in mountainous, hilly and rugged areas. The first alternative method that might be used in such regions is the PTL. PTL method is more flexible than GL and reaches the GL

[^2]accuracy by making the zenith angle measurements carefully, simultaneously and reciprocally using a special equipments and by selecting the length of sight shorter than 500 m
